A quest in the player's language.

- A real mod-localisation need: create reusable drafts without breaking game variables, colours or book commands.
- New standalone MIT prototype. The pre-existing AGPL AutoTranslation mod stays separate.
- An open model, immutable syntax, visible errors and a verifiable cache. Every draft needs linguistic review.

github.com/yuefdev/questbridge-amd

Recorded application output

- Forge quest -> German draft.
- Eight game tokens preserved.
- Repeat -> verified cache hit.
- Actual saved screenshot, not a fabricated live result.

What actually ran on AMD

- AMD Ryzen 9 7950X3D / llama.cpp b11624 / Qwen3-4B-Instruct-2507 Q4_K_M / CPU only.
- Final recording: 4 unique model calls, 2 format-valid drafts, 2 unchanged-English rejections and 1 cache hit.
- 5 focused tests passed. Raw inputs, returned text, timings and unsuccessful trials are published.
- No unmeasured speedup, quality score or GPU result is claimed.

Review first. Evidence stays visible.

- Turkish draft quality is weak; fixed fragment boundaries can produce awkward word order. Do not ship unreviewed output.
- AMD Token Factory account assignment is pending. Local CPU evidence does not establish cloud/GPU access.
- Next milestone: provision the AMD endpoint, improve full-sentence localisation and measure against reviewed translations.
- Original samples and MIT source are reproducible. AI coding assistance is disclosed.
